# Data Transmission

# Data Transmission

Inside the CPU or Microcontroller data is transmitted in Parallel using Buses (8/16/32 Bit). For long distances we use a single wire and serial transmission.

# Serial Data Transmission

We can use our Digital Input and Output Pins to transmit data from one Microcontroller to the other.

We need to write a piece of software to convert an 8-Bit integer value (`int x=0xA5;`) into 8 single bits, we do not use 1 Bit (boolean) arrays to store numbers!

Decimal 47 → 00101111b  
↓                  ↓  
3.3V              0V

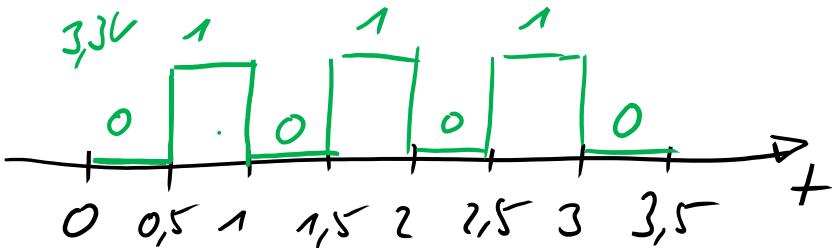

We need to use the Modulus Operator **%** and the Shift Operator **<< left - right >>**

<https://www.geeksforgeeks.org/bitwise-operators-in-c-cpp/>

# Data Transmit

```
#include "mbed.h"  
PA-5  
DigitalOut led(LPE1);  
bool b[10]{0,1,0,1,0,1,0,1,0,1}; // Boolean Array initialised  
  
int main() {  
    while (1) {  
        for(int i=0; i<10; i++)  
        {  
            led = b[i];  
            wait_ms(500);  
        }  
        wait_ms(2000);  
    }  
}
```

// wait to see that the for loop has finished

# Data Transmit – Modulo & Shift

```
#include "mbed.h"
```

```
DigitalOut led(LED1);  
int x=0xA5; // 1010 0101b  
int y=0; // 0x61 0110 0001b
```

```
int main() {  
    while (1) {  
        y = x %2; // Modulo Operator ! y=1  
        if (y)  
        { led = 1; } // odd number -> Bit 0 == 1 -> LED on  
        else  
        { led = 0; } // even number -> Bit 0 == 0 -> LED off  
        x = x >> 1; // Shift right -> next Bit  
        wait_ms(500);  
    } // 1/↑ X 0101 0010b
```

## Point-to-Point Connection / Transmission

The Transmit-Pin (Tx) from the Sender hast to be connected with the Receive-Pin (Rx) from the Receiver.

Asynchronus works without a clock signal that shows when the data is valid. As a result both microcontrollers need to use the same data transmission rate well known as the baudrate !

(Typical values are 9600 // 19200 // 57600 // 115200)

# USART – STM32

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a fractional baud rate generator.

It supports synchronous one-way communication and half-duplex single wire communication. It also supports the LIN (local interconnection network), Smartcard Protocol and IrDA (infrared data association) SIR ENDEC specifications, and modem operations (CTS/RTS). It allows multiprocessor communication.

High speed data communication is possible by using the DMA for multibuffer configuration.

**RX:** Receive Data Input is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

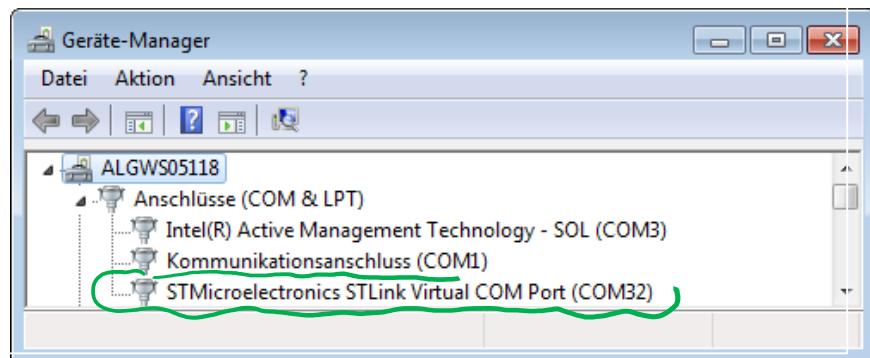

**TX:** Transmit Data Output. When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire and smartcard modes, this I/O is used to transmit and receive the data (at USART level, data are then received on SW\_RX).

# USART – STM32 - mbed

Example 3)

Configure a second USART

Transmit the Character „a“ within an infinite loop  
every 2ms -> wait\_ms(2);

Attach the LEO-Oscilloscope to show the signal.

# USART – STM32 - mbed

# USART – STM32 - mbed

## Example 4)

Read a number from the Terminal

The led should toggle as many times as the value that has been transmitted

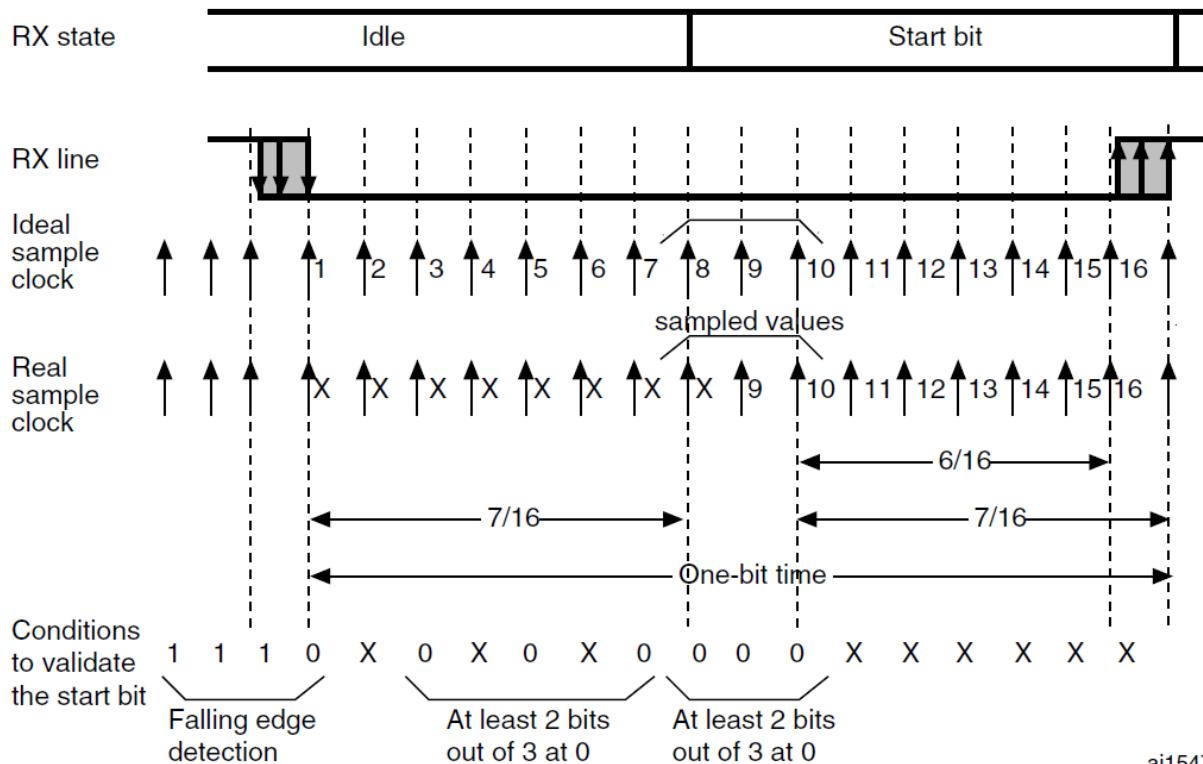

$$'1' - '9'$$

$$\Rightarrow i = c - '0'$$

$$i = c - 48$$

$$i = c - 0x30$$

# USART – STM32 – Start Bit detection

ai15471

# USART – STM32 – Start Bit detection

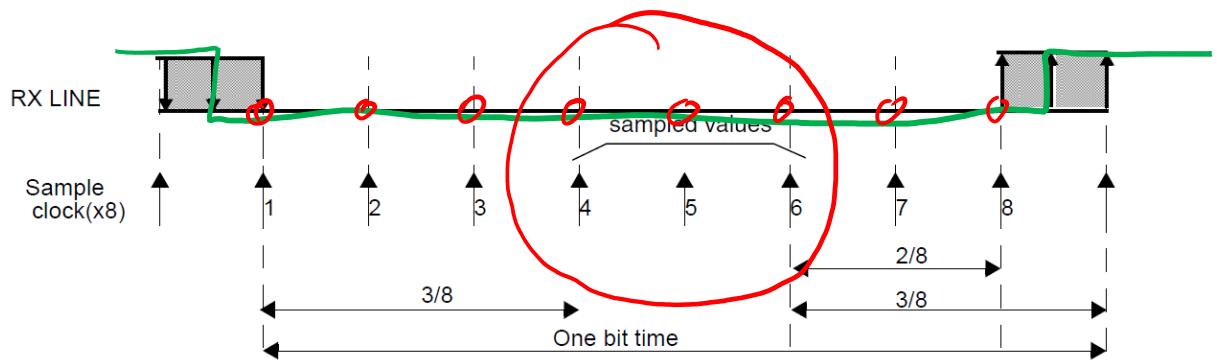

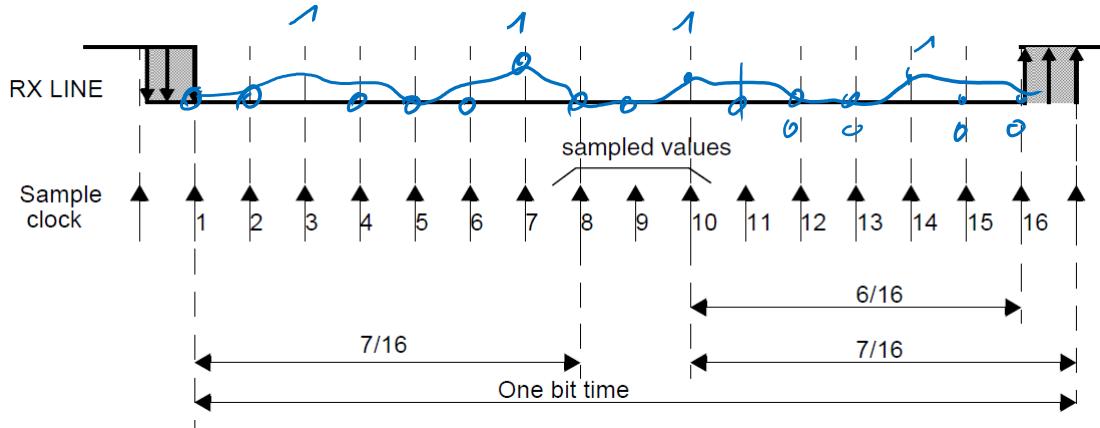

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0 X 0 0 0 0.

*If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set) where it waits for a falling edge.*

*The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).*

# USART – STM32 – Oversampling

# USART – STM32 – Noise detection

Table 107. Noise detection from sampled data

| Sampled value | NE status | Received bit value |
|---------------|-----------|--------------------|
| 000           | 0         | 0                  |
| 001           | 1         | 0                  |
| 010           | 1         | 0                  |
| 011           | 1         | 1                  |

| 111           | 0         | 1                  |

# USART – STM32 – Wrong Bit?

# USART – STM32 – Parity Control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART\_CR1 register. Depending on the frame length defined by the M bit, the possible USART frame formats are as listed in *Table 120*.

**Table 120. Frame formats**

| M bit | PCE bit | USART frame <sup>(1)</sup> |
|-------|---------|----------------------------|
| 0     | 0       | SB   8 bit data   STB      |
| 0     | 1       | SB   7-bit data   PB   STB |
| 1     | 0       | SB   9-bit data   STB      |
| 1     | 1       | SB   8-bit data   PB   STB |

1. Legends: SB: start bit, STB: stop bit, PB: parity bit.

# USART – STM32 – Parity Control

## Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

E.g.: data=00110101; 4 bits set => parity bit will be 0 if even parity is selected (PS bit in USART\_CR1 = 0).

## Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

E.g.: data=00110101; 4 bits set => parity bit will be 1 if odd parity is selected (PS bit in USART\_CR1 = 1).

# USART – STM32

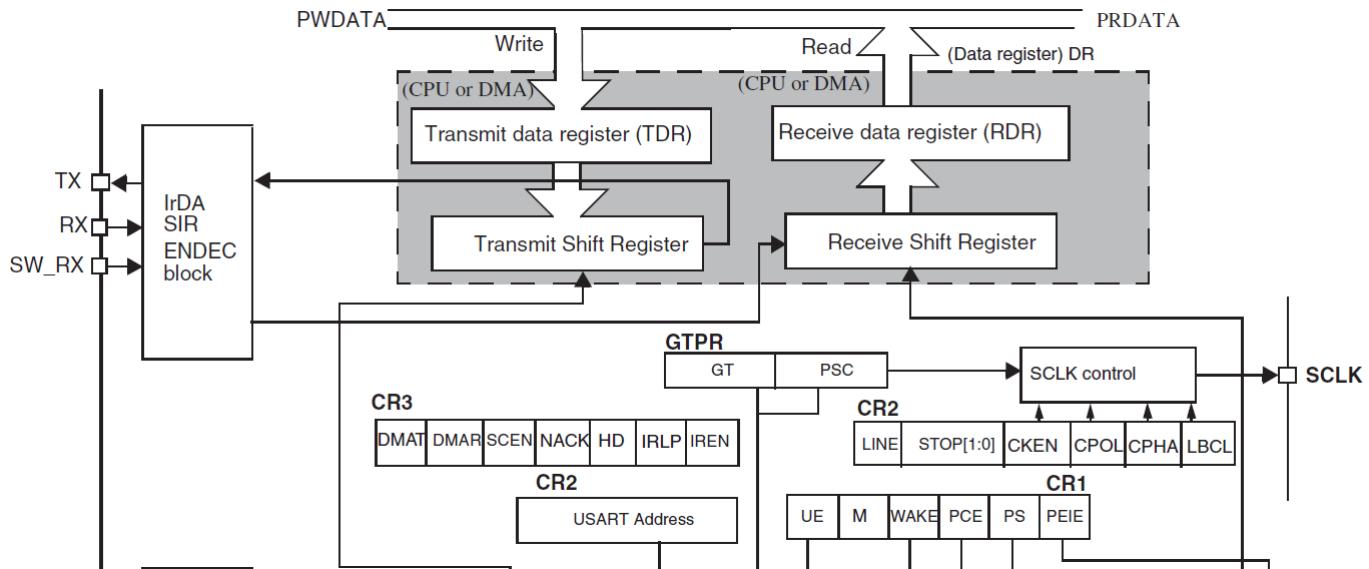

## Parity checking in reception

If the parity check fails, the PE flag is set in the USART\_SR register and an interrupt is generated if PEIE is set in the USART\_CR1 register. The PE flag is cleared by a software sequence (a read from the status register followed by a read or write access to the USART\_DR data register).

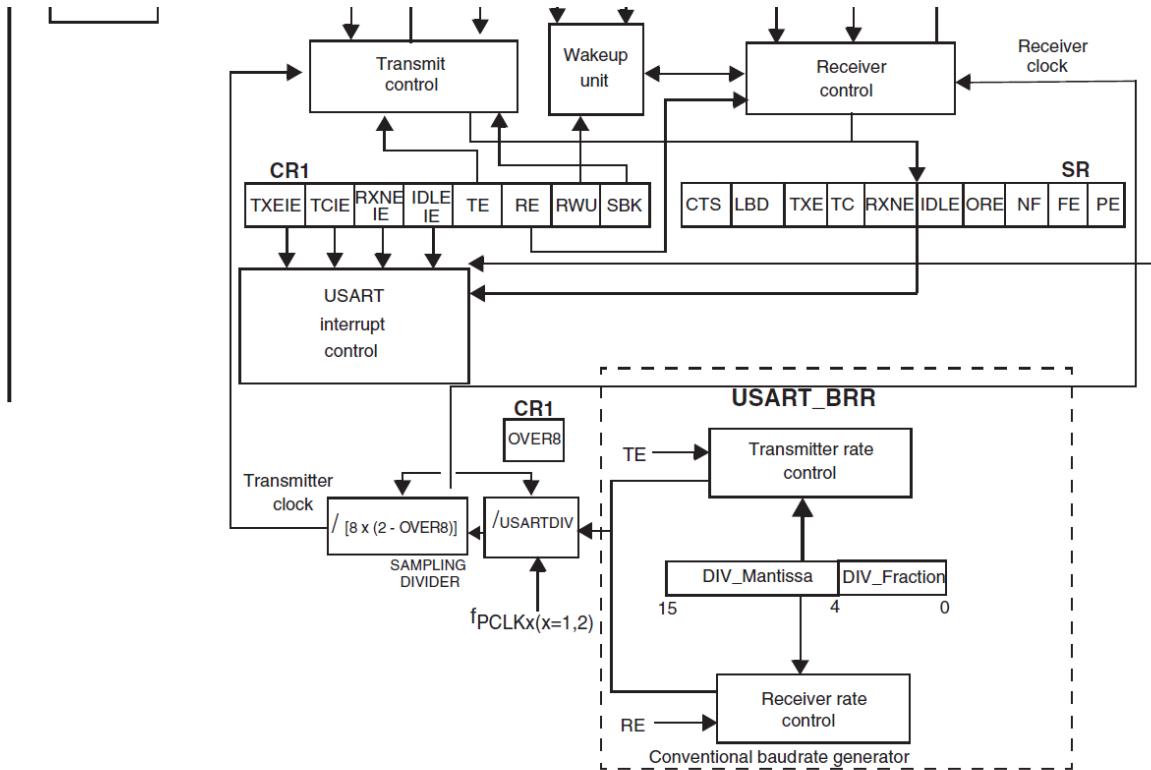

## Parity generation in transmission

If the PCE bit is set in USART\_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

# I<sup>2</sup>C / NXP UM10204

# I<sup>2</sup>C NXP UM10204

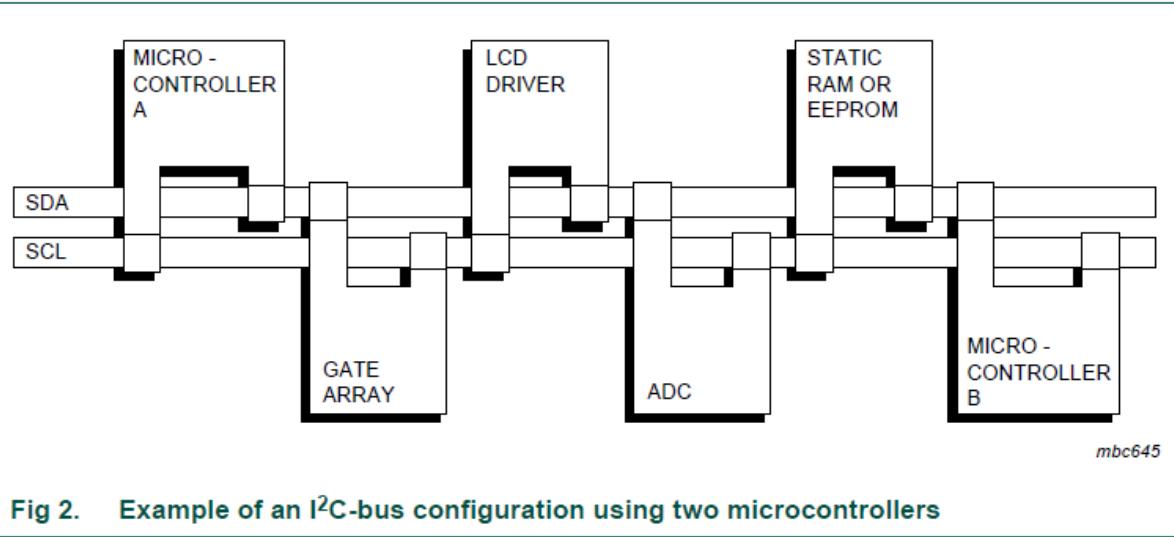

Fig 2. Example of an I<sup>2</sup>C-bus configuration using two microcontrollers

# I<sup>2</sup>C Open Drain – Mastering STM32

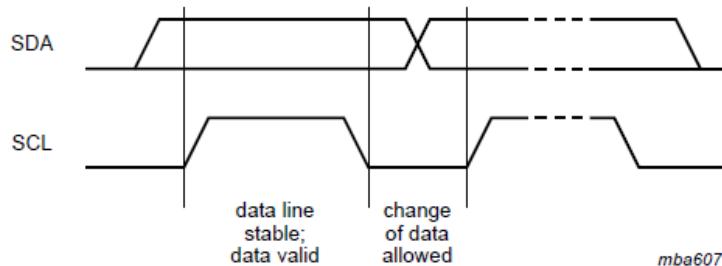

The effectiveness of the ACK/NACK bit is due to the *open-drain* nature of the I<sup>2</sup>C protocol. *Open-drain* means that both master and slave involved in a transaction can pull the corresponding signal line LOW, but cannot drive it HIGH. If one between the transmitter and receiver releases a line, it is automatically pulled HIGH by the corresponding resistor if the other does not pull it LOW. The *open-drain* nature of the I<sup>2</sup>C protocol also ensures that there can be no bus contention where one device is trying to drive the line HIGH while another tries to pull it LOW, eliminating the potential for damage to the drivers or excessive power dissipation in the system.

# I<sup>2</sup>C NXP UM10204

## Data validity

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW (see [Figure 4](#)). One clock pulse is generated for each data bit transferred.

**Fig 4.** Bit transfer on the I<sup>2</sup>C-bus

# I2C NXP UM10204

## START and STOP conditions

All transactions begin with a START (S) and are terminated by a STOP (P) (see [Figure 5](#)). A HIGH to LOW transition on the SDA line while SCL is HIGH defines a START condition. A LOW to HIGH transition on the SDA line while SCL is HIGH defines a STOP condition.

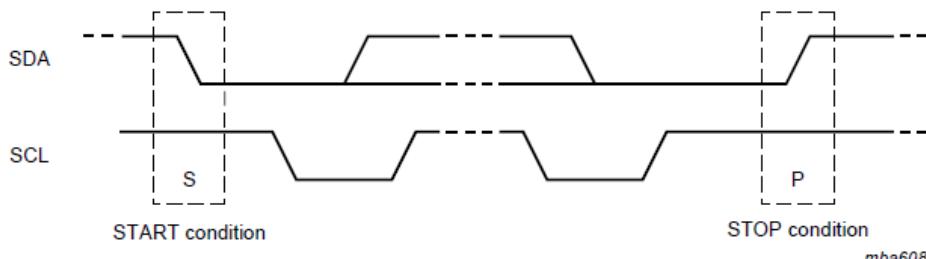

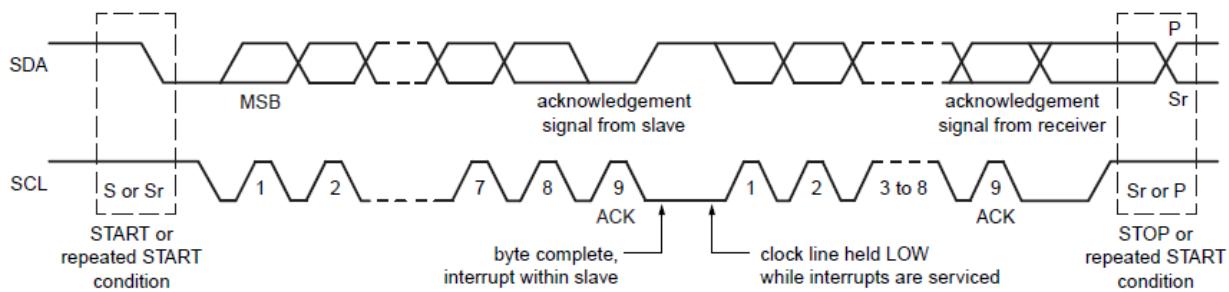

Fig 5. START and STOP conditions

START and STOP conditions are always generated by the master. The bus is considered to be busy after the START condition. The bus is considered to be free again a certain time after the STOP condition. This bus free situation is specified in [Section 6](#).

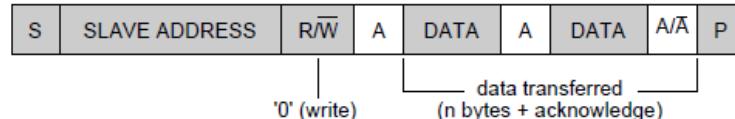

# I<sup>2</sup>C NXP UM10204

Every byte put on the SDA line must be eight bits long. The number of bytes that can be transmitted per transfer is unrestricted. Each byte must be followed by an Acknowledge bit. Data is transferred with the Most Significant Bit (MSB) first (see [Figure 6](#)). If a slave cannot receive or transmit another complete byte of data until it has performed some other function, for example servicing an internal interrupt, it can hold the clock line SCL LOW to force the master into a wait state. Data transfer then continues when the slave is ready for another byte of data and releases clock line SCL.

## Device ID

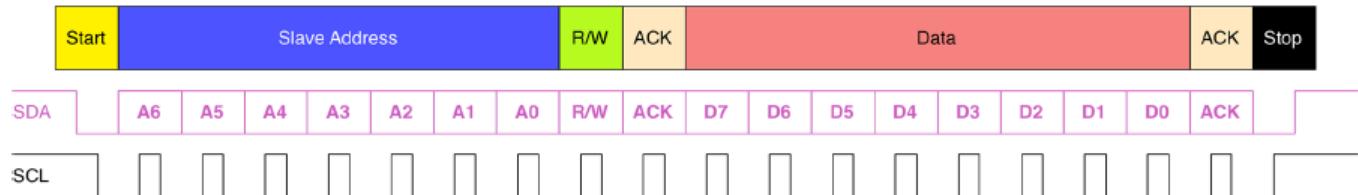

The Device ID field (see [Figure 20](#)) is an optional 3-byte read-only (24 bits) word giving the following information:

- Twelve bits with the manufacturer name, unique per manufacturer (for example, NXP)
- Nine bits with the part identification, assigned by manufacturer (for example, PCA9698)
- Three bits with the die revision, assigned by manufacturer (for example, RevX)

**Fig 20. Device ID field**

# I2C Mastering STM32

# I<sup>2</sup>C – Mastering STM32 – Read Data

This communication schema has a great pitfall: if we want to ask something specific to the slave device we need to use two separated transactions. Let us consider this example. Suppose we have an I<sup>2</sup>C EEPROM. Usually this kind of devices has a number of addressable memory locations (a 64Kbits EEPROM is addressable in the range 0 - 0xFFFF<sup>10</sup>). To retrieve the content of a memory location, the master should perform the following steps:

- start a transaction in write mode (last bit of the slave address set to 0) by sending the slave address on the I<sup>2</sup>C bus so that the EEPROM begins sampling the messages over the bus;
- send two bytes representing the memory location we want to read;
- end a transaction by sending a STOP condition;
- start a new transaction in read mode (last bit of the slave address set to 1) by sending the slave address on the I<sup>2</sup>C bus;
- read  $n$ -bytes (usually one if reading the memory in random mode, more than one if reading it in sequential mode) sent by the slave device and then ending the transaction with a STOP condition.

# I<sup>2</sup>C – Mastering STM32 – Read Data

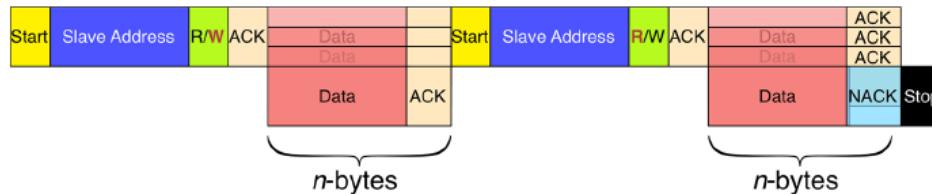

Figure 5: The structure of a *combined transaction*

To support this common communication schema, the I<sup>2</sup>C protocol defines the *combined transactions*, where the direction of data flow is inverted (usually *from slave to master*, or vice versa) after a number of bytes have been transmitted. Figure 5 schematizes this way to communicate with slave devices. The master starts sending the slave address in write mode (note the W in red-bold in Figure 5) and then sends the addresses of registers we want to read. Then a new START condition is sent, without terminating the transaction: this additional START condition is also called *repeated START condition* (or RESTART). The master sends again the slave address but this time the transaction is started in read mode (note the R in bold in Figure 5). The slave now transmits the content of wanted registers, and the master acknowledges every byte sent. The master ends the transaction by issuing a NACK (this is really important, as we will see next) and a STOP condition.

# I2C – Mastering STM32 – Read Data

```
HAL_StatusTypeDef Read_From_24LCxx(I2C_HandleTypeDef *hi2c, uint16_t DevAddress, uint16_t MemAddress, uint8_t *pData, uint16_t len) {
    HAL_StatusTypeDef returnValue;
    uint8_t addr[2];

    /* We compute the MSB and LSB parts of the memory address */
    addr[0] = (uint8_t) ((MemAddress & 0xFF00) >> 8);
    addr[1] = (uint8_t) (MemAddress & 0xFF);

    /* First we send the memory location address where start reading data */
    returnValue = HAL_I2C_Master_Transmit(hi2c, DevAddress, addr, 2, HAL_MAX_DELAY);
    if(returnValue != HAL_OK)
        return returnValue;

    /* Next we can retrieve the data from EEPROM */
    returnValue = HAL_I2C_Master_Receive(hi2c, DevAddress, pData, len, HAL_MAX_DELAY);

    return returnValue;
}
```

# I<sup>2</sup>C - HTS221

Figure 1. HTS221 block diagram

# I<sup>2</sup>C - HTS221

The I<sup>2</sup>C embedded in the HTS221 behaves like a slave device and the following protocol must be adhered to. After the start condition (ST) a slave address is sent, once a slave acknowledge (SAK) has been returned, an 8-bit sub-address (SUB) will be transmitted: the 7 LSB represents the actual register address while the MSB enables address auto-increment. If the MSB of the SUB field is '1', the SUB (register address) will be automatically increased to allow multiple data read/write.

| Command | SAD[6:0] | R/W | SAD+R/W        |
|---------|----------|-----|----------------|
| Read    | 1011111  | 1   | 10111111 (BFh) |
| Write   | 1011111  | 0   | 10111110 (BEh) |

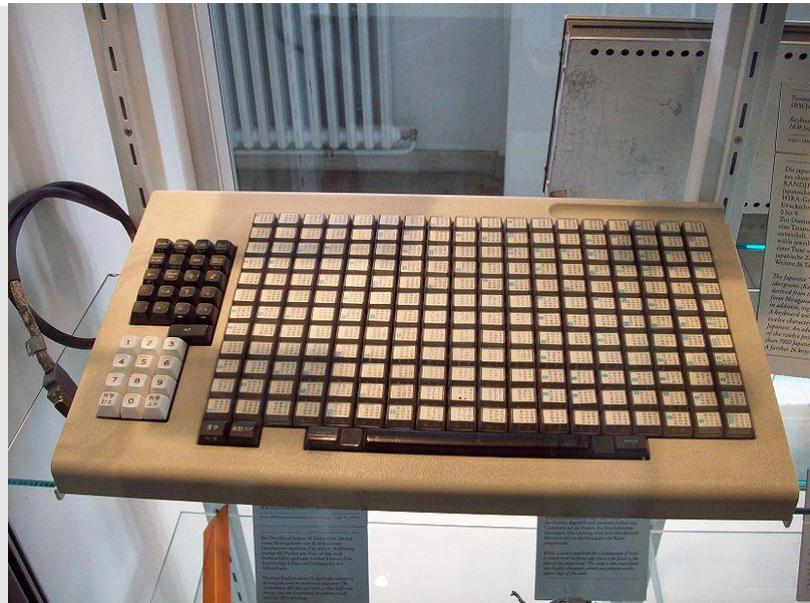

**Table 13. Transfer when master is receiving (reading) one byte of data from slave**

| Master | ST | SAD + W |     | SUB |     | SR | SAD + R |     |      | NMAK | SP |

## PS/2 – Keyboard

Thomas Fischer

<http://www.marjorie.de/ps2/start.htm>

<http://www.computer-engineering.org/>

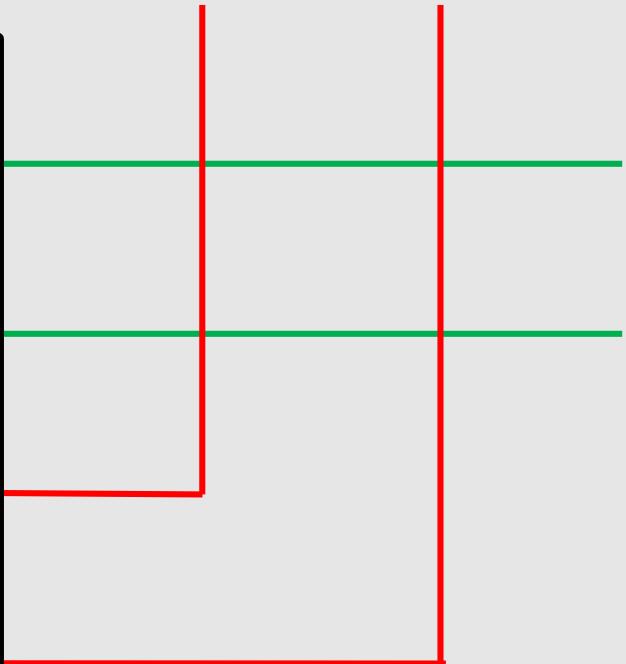

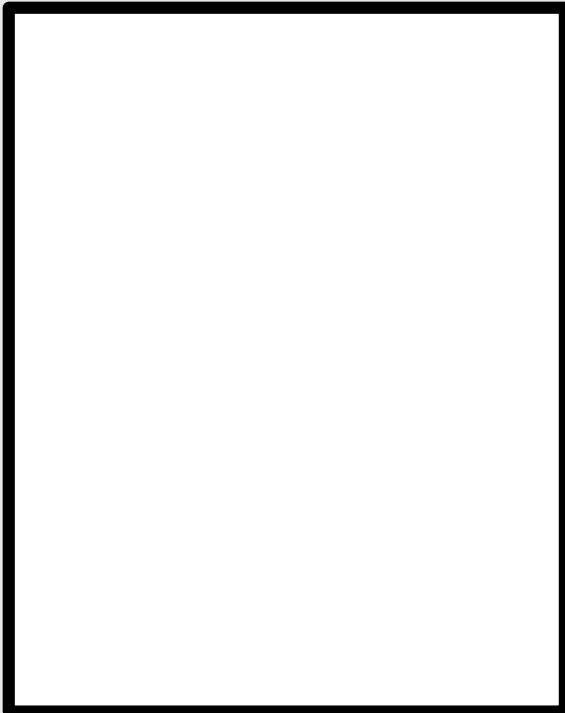

<http://www.schatenseite.de/mamecontrol.html>

<http://de.wikipedia.org/wiki/Tastatur>

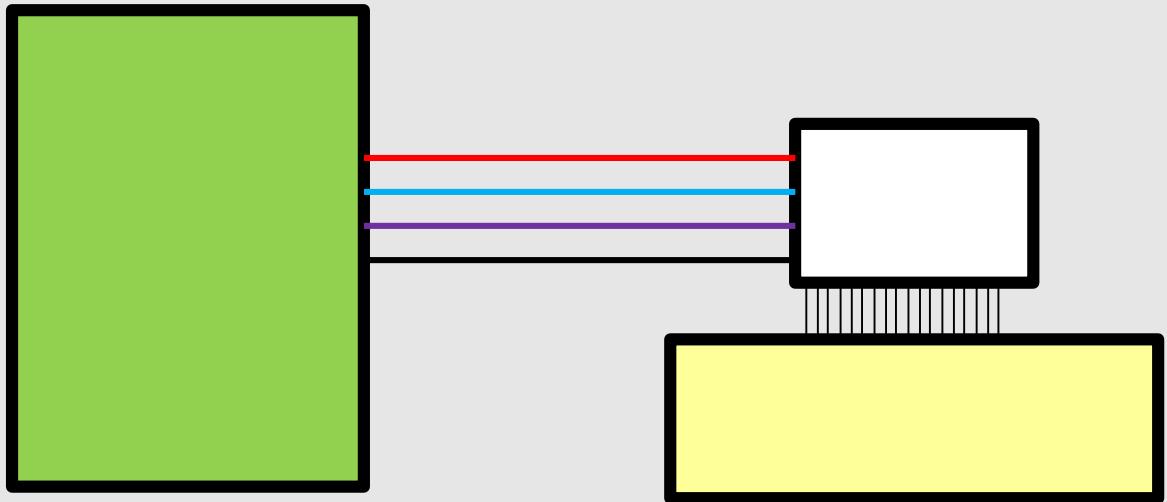

## PS/2 Keyboard

- > If every key would be connected to one pin you would need a controller with 100pins. Within an infinite loop you could poll every pin. -> not the best solution!
- > Better solution is to use the keys as connectors between rows and columns ([matrix](#)), 10 each. If a key is pressed down there will be a connection between one row and one column. Within an infinite loop you set one row to zero and ask all columns if their level is forced to zero. Now you need only 20 pins!
- > A microcontroller (XT-keyboards an 8042) is sending this information to the PC using a [Scancode](#).

## PS/2 Keyboard

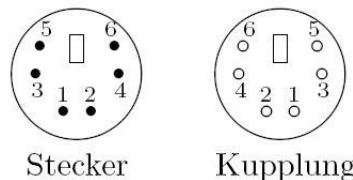

## PS/2 Keyboard

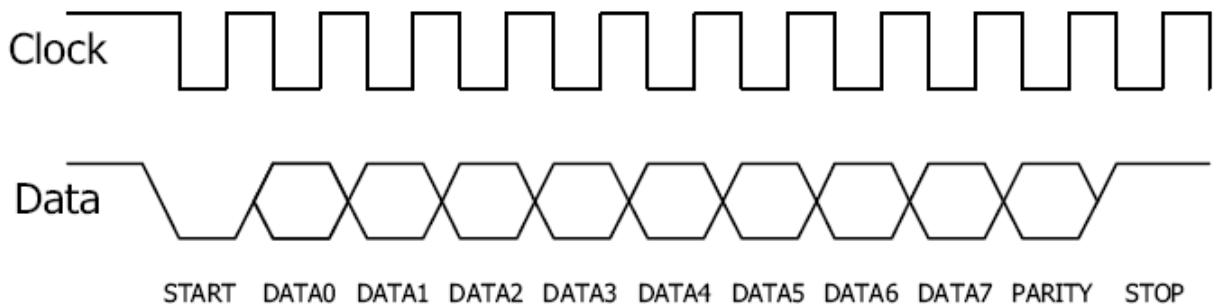

## PS/2 Keyboard

- > Clock is zero when data is valid
- > Data line – transmit data bit by bit (serial transmission)

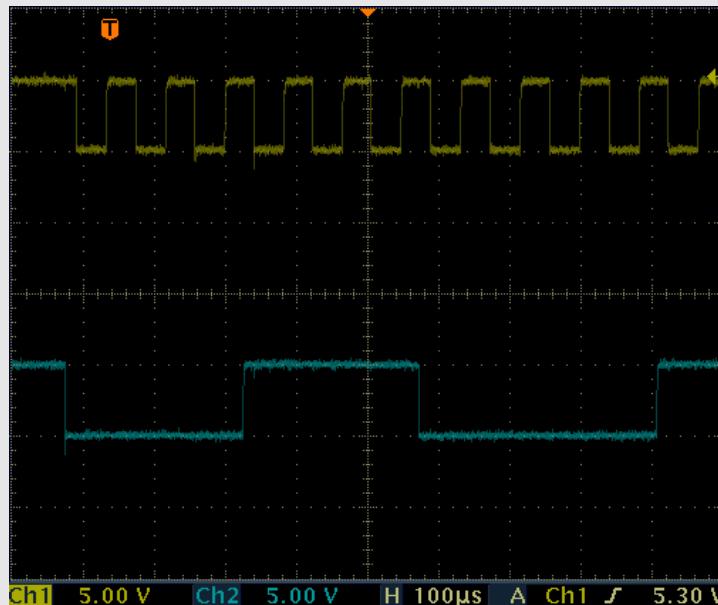

**6-pin Mini-DIN (PS/2):**

- 1 - Data
- 2 - nicht belegt
- 3 - Ground
- 4 -  $V_{CC}$  (+5 V)
- 5 - Clock
- 6 - nicht belegt

## PS/2 Keyboard

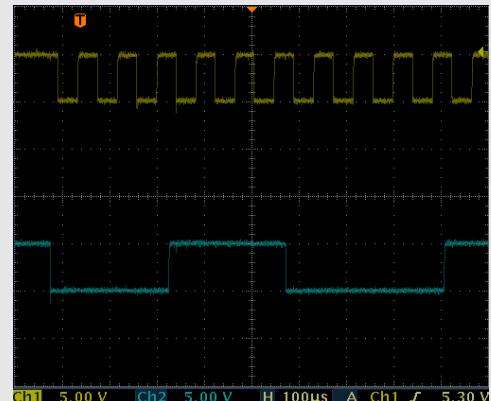

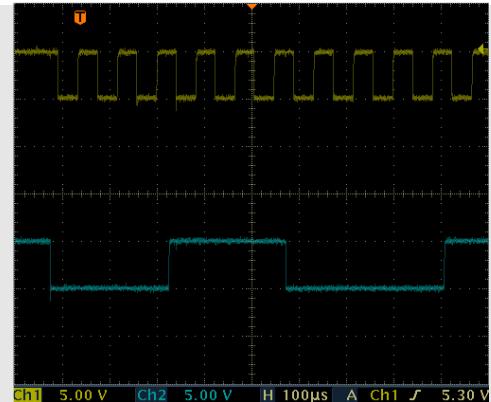

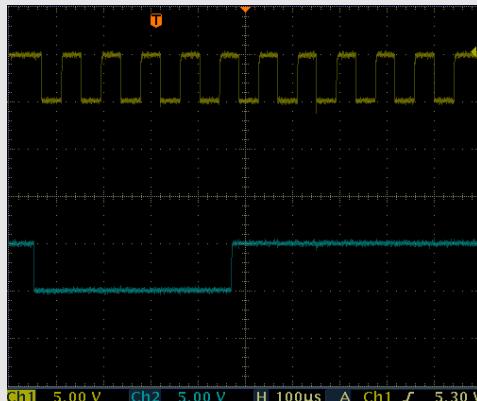

- > If key is pressed down the Make Code (1Ch) will be transmitted

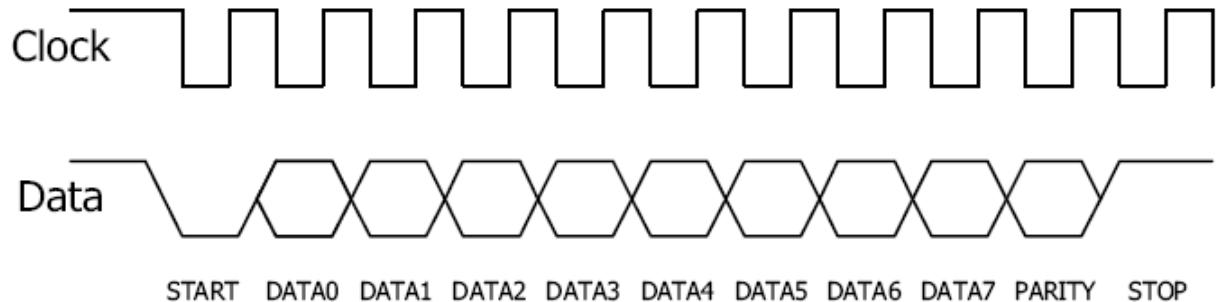

## PS/2 Keyboard

- > If key is pressed down the Make Code (1Ch) will be transmitted - (1 Byte)
- > If key is released the Break Code will be transmitted 2 Byte F0h and 1Ch

$$f = 10k - 16,7k \text{ Hz}$$

## PS/2 Keyboard - Software

## Example - PS/2 Keyboard

- > Write 2 ISRs to check which line ist the data line and which is the clock line
- > Write a program to get 33 EXTI IRQs from the clock line.  
If the counter variable I=33 toggle LED green.
- > If key „a“ is pressed the Bitstream schould be „1C“  
=> 2 rising and 2 falling edges on the data line  
toggle LED red.

## Example - PS/2 Keyboard

- > Start with Flow chart!
- > Try to receive any key first!
- > If key „a“ is pressed LED red should toggle.
- > If key „e“ is pressed LED green should be turned on.
- > If key „i“ is pressed LED green should be turned off.
- > Write a program to get all 26 letters.

## PS/2 Keyboard – ISR – Bad Code! – Why?

```
//————— Interrupt service routine for EINT0 —————//
void isr_int0(void) __irq
{
    unsigned char i;                      // Define for counter loop
    if(_inp0(16)==0)                      // Check start bit true?
    {
        while(_inp0(16)==0);              // wait for "1" after start bit
        for(i=0;i<10;i++)                // For loop count 10 time(for receive data 8 bit)
        {
            while(_inp0(16)==1);          // wait for "0" after data bit
            _code = _code>>1;             // Shift data bit to right 1 time
            if(_inp0(15))
                _code = _code | 0x8000;    // Config data bit = "1"
            while(_inp0(16)==0);          // wait for "1" after data bit
        }
        while(_inp0(16)==0);              // wait for "1" after stop bit
        _code = _code>>6;
        _code &= 0x00FF;
    }
    EXTINT |= 0x1;                        // Clear interrupt flag EINT0
    VICVectAddr = 0;                      // Acknowledge Interrupt
}
```

# **Serial Communication**
